**Note: This course covers circular pipe conduits.
Future courses will address other conduit shapes.**

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Purpose

Although the force of gravity is nearly constant in magnitude and direction, we can redirect gravity's vertical force to power the transport of liquids in a sloped pipe over great distances. The purpose of this course and the companion software is to examine and understand one approach to the hydraulic design of such pipelines. The Manning formula is one of many empirical formulae that science and engineering have developed to predict the velocity of gravity flow in a conduit.

The person who completes this course will have an improved understanding of the hydraulics of gravity pipelines and the use of the Manning Formula as a design tool. The Manning-Pipe software will allow users to speed the learning by eliminating most of the monotonous calculation.

Introduction

The Manning Formula, developed in 1890 by the Irish accountant turned engineer, Robert Manning, was a refinement of the 1867 formula developed by French engineer Philippe Gauckler. Although Manning had no formal education in engineering or hydraulics, he was a methodical mathematician and a keen observer. In addition to Gauckler, his formula was derived as a compilation of seven other empirical formulae (see inset) that were in use during the period. Common uses for Manning's formula are the design of gravity flow conduits such as storm sewers, sanitary sewers, swales, ditches and rivers. The formula takes two basic forms as follows:

Manning's Formula is a compilation of these formulae:

- Du Buat (1786)
- Eyelwein (1814)
- Weisbach (1845)
- St. Venant (1851)
- Neville (1860)
- Darcy and Bazin (1865)
- Ganguillet & Kutter (1869)

In U.S. Customary Units

(1) $V = \frac{1.486}{n} \times R^{2/3} \times S^{1/2}$

(2) $Q = AV = \frac{1.486}{n} A \times R^{2/3} \times S^{1/2}$

Where:

V=Mean velocity in feet per second
n=Manning coefficient of roughness
R=Hydraulic radius in feet (the cross-

In Metric Units

$V = \frac{1}{n} \times R^{2/3} \times S^{1/2}$

$Q = AV = \frac{1}{n} A \times R^{2/3} \times S^{1/2}$

Where:

V=Mean velocity in meters per second
n=Manning coefficient of roughness
R=Hydraulic radius in meters (the cross-

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

sectional area of flow divided by the wetted perimeter)

sectional area of flow divided by the wetted perimeter)

S=Hydraulic slope in feet per foot (or any other linear measure divided by the same linear measure). This is an indication of the loss of head in the system.

S=Hydraulic slope in meters per meter (or any other linear measure divided by the same linear measure). This is an indication of the loss of head in the system.

Q=Quantity of flow in cubic feet per second

Q=Quantity of flow in cubic meters per second

A=Cross-sectional area of flow in square feet.

A=Cross-sectional area of flow in square meters.

Formula (1) above may be restated as follows:

In U.S. Customary Units

In Metric Units

$$(3) \quad n = \frac{1.486}{V} \times R^{2/3} \times S^{1/2}$$

$$n = \frac{1}{V} \times R^{2/3} \times S^{1/2}$$

$$(4) \quad R = \left(\frac{Vn}{1.486 \times S^{1/2}} \right)^{3/2}$$

$$R = \left(\frac{Vn}{S^{1/2}} \right)^{3/2}$$

$$(5) \quad S = \left(\frac{Vn}{1.486 \times R^{2/3}} \right)^2$$

$$S = \left(\frac{Vn}{R^{2/3}} \right)^2$$

The SunCam “Manning-Pipe” software was developed using these formulae and the geometry of a circle. Iterative approximation methods have been utilized to find some solutions. Solutions utilizing these methods are generally accurate to within ±0.01%.

The input tracking cells (rows 33 & 34) prompt the user about the status of inputs. The tracking cell at row 33 will always display one of the following prompts:

Let's Get Started! – When no input data has been entered.

Complete Results – When the user has input sufficient data to generate complete results.

Need More Data – When data input is insufficient to generate any results.

Partial Results! – When the input data is sufficient to generate some (but not all) results.

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Over Determined – When too many input cells have input.

The tracking cell at row 34 will remain blank or display one of the following prompts:

Please Input Your Known Data - When no input data has been entered.

A second solution will display when % full is at or above XX.xx% - When the input data could result in 2-possible solutions. The percentage displayed depends on which combination of variables you input. (More on that later)

Too Much Input Data (Q, V, a) – When too much data has been input. (The variables in parentheses are the input combinations that make the problem over determined.)

Percentages

A note about entering percentages in an Excel spreadsheet:

You can set Excel to enter percentages as either a whole number (5=5%) or a decimal (.05=5%).

For Excel 2007:

1. Click the office button in the upper left of the screen ->
2. Click Excel Options at the bottom of the dropdown ->
3. Click Advanced ->
4. In "Editing Options" check or uncheck the box labeled "Enable automatic percent entry" to make the change.
5. If you are using another version of Excel you can use "Help" to find where to make the changes.

Figure 1 Sample inputs and results using Manning-Pipe

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Manning Formula

This empirical formula uses three variables ("n", "R" & S) to calculate the velocity of flow in a pipe. When the cross-sectional area of flow is known it can be multiplied by the velocity to determine the quantity of flow ($Q=aV$). Although this course will be limited to circular pipe, the conduit could also be a box culvert, a ditch or a river. Flow through a conduit with a free water surface such as ditches, rivers and partially filled pipes and culverts is generally called "open channel flow" while flow through full pipes and culverts is called "closed channel flow".

The Variables

Coefficient of Roughness (n) - Of the three variables ("n", "R" & S), "n", the coefficient of roughness, is the most difficult for the engineer to determine with accuracy and therefore should be the most carefully examined of the three. For new pipe, the manufacturer will supply the most accurate value for "n" but the engineer would be wise to consider how the roughness coefficient will change over the years following installation. Post installation factors that affect the value of the roughness coefficient include:

1. Solids collecting in the bottom (obvert) of the pipe or on its walls
2. Settlement or deflection of the pipe
3. Tree roots growing into the pipe through pipe joints or cracks
4. Erosion of the pipe interior surface

As the design engineer, you will use your own judgment to select the most appropriate coefficient for your project. We encourage you to test a range of values before making your decision. For this course, we will use the following values for *n*:

| | |
|-----------------------|----------------|
| Polyethylene (smooth) | 0.009 |
| PVC | 0.010 |
| Asbestos cement | 0.011 |
| Cast iron | 0.012 |
| Concrete | 0.012 or 0.013 |
| Clay | 0.014 |
| Corrugated metal | 0.022 |

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Hydraulic Radius (R) - The hydraulic radius is defined as the cross sectional area of the stream of water ("a") divided by the wetted perimeter ("p"). In U.S. customary units, the hydraulic radius is always measured in feet. So, for a 24-inch diameter pipe flowing full, "R" would be calculated as follows:

$$(7) a = \pi \left(\frac{r}{12}\right)^2 = 3.14159 \text{ ft}^2$$

$$(8) \text{Wetted Perimeter} = \pi \frac{d}{12} = 6.28318 \text{ ft}$$

$$(9) R = \frac{3.14159 \text{ ft}^2}{6.28318 \text{ ft}} = 0.5 \text{ ft}$$

For the same pipe flowing half full, the calculation of (R) would similarly be:

$$(10) R = \frac{\frac{3.14159 \text{ ft}^2}{2}}{\frac{6.28318 \text{ ft}}{2}} = 0.5 \text{ ft}$$

Use the Manning-Pipe software to verify these results. Enter:

- [24] in the input cell for pipe diameter ("d")in inches (don't enter the [brackets])
- [100] in the input cell for "%" Full (*or [1.0] depending on your Excel setup, See Percentage note on page 4*)

Figure 2 below shows the solution.

| | | | | |
|---------------------------------|------------|-------------|--|---------------|
| R Hydraulic Radius (a/p) | | 0.5 | | Feet |
| | | 0.152401853 | | Meters |
| d Pipe Diameter | 24 | 24 | | Inches |
| | | 609.6012192 | | Millimeters |
| % % Full | 100.00000% | 100.00000% | | % Full |
| h Depth of Flow | | 24 | | Inches |
| | | 609.6012192 | | Millimeters |
| a Area of Flow | | 3.141592654 | | Square Feet |
| | | 0.291861079 | | Square Meters |
| p Wetted Perimeter | | 6.283185307 | | Feet |
| | | 1.91513817 | | Meters |

Figure 2 Computing "R" for pipe flowing full

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Now change the percentage full entry to:

- [50] in the input cell for "%" Full (or [0.5] depending on your Excel setup, See Percentage note on page 4)
- Figure 3 below shows the solution.

| | | | | |
|------------------------|-----------|-------------|--|---------------|
| Hydraulic Radius (a/p) | | 0.5 | | Feet |
| | | 0.152401853 | | Meters |
| Pipe Diameter | 24 | 24 | | Inches |
| | | 609.6012192 | | Millimeters |
| % Full | 50.00000% | 50.00000% | | % Full |
| Depth of Flow | | 12 | | Inches |
| | | 304.8006096 | | Millimeters |
| Area of Flow | | 1.570796327 | | Square Feet |
| | | 0.145930539 | | Square Meters |
| Wetted Perimeter | | 3.141592654 | | Feet |
| | | 0.957569085 | | Meters |

Figure 3- Computing "R" for pipe flowing half full

The hydraulic radius for a full pipe is always identical to that of a pipe flowing half full, which means the velocity will be the same if "n" and "S" are constant. Likewise, the quantity of flow, "Q", for a full pipe will always be twice the flow of a half-full pipe because the cross sectional area of flow doubles when the pipe is full.

Exploring hydraulic radius further, we will build a table of values for area ("a"), wetted perimeter ("p") and hydraulic radius ("R") using various percentages full and the same 24-inch diameter pipe:

| % Full | a | p | R |
|--------|--------|--------|--------|
| 10% | 0.1635 | 1.2870 | 0.1270 |
| 20% | 0.4473 | 1.8546 | 0.2412 |
| 30% | 0.7927 | 2.3186 | 0.3419 |
| 40% | 1.1735 | 2.7389 | 0.4285 |
| 50% | 1.5708 | 3.1416 | 0.5000 |
| 60% | 1.9681 | 3.5443 | 0.5553 |
| 70% | 2.3489 | 3.9646 | 0.5925 |
| 80% | 2.6943 | 4.4286 | 0.6084 |
| 90% | 2.9781 | 4.9962 | 0.5961 |
| 100% | 3.1416 | 6.2832 | 0.5000 |

Table 1 - "%" full vs. Hydraulic Radius

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

You will notice that "R" values increase with the percentage full up to 80% and then decrease to 0.5 at 100%. Actually, the maximum value for "R" for any size round pipe occurs when the pipe is 81.28% full.

| % Full | a | p | R |
|---------------|---------------|---------------|---------------|
| 10% | 0.1635 | 1.2870 | 0.1270 |
| 20% | 0.4473 | 1.8546 | 0.2412 |
| 30% | 0.7927 | 2.3186 | 0.3419 |
| 40% | 1.1735 | 2.7389 | 0.4285 |
| 50% | 1.5708 | 3.1416 | 0.5000 |
| 60% | 1.9681 | 3.5443 | 0.5553 |
| 70% | 2.3489 | 3.9646 | 0.5925 |
| 80% | 2.6943 | 4.4286 | 0.6084 |
| 81.28% | 2.7348 | 4.4934 | 0.6086 |
| 90% | 2.9781 | 4.9962 | 0.5961 |
| 100% | 3.1416 | 6.2832 | 0.5000 |

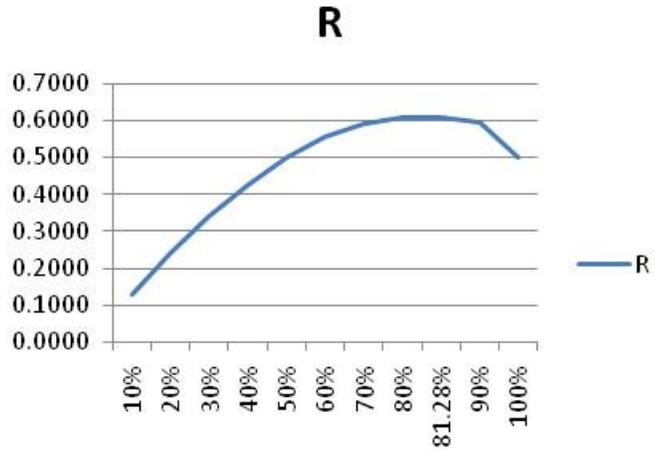

Table 2 - The maximum value of R

This would also be the point of maximum velocity (but not the point of maximum quantity of flow).

The shape of the chart in Table 2 above demonstrates the reason that there are sometimes two sets of results for a given set of input data. Use Manning-Pipe to illustrate this point by entering:

- [24] in the input cell for pipe diameter ("d") in inches
- [0.55] in the input cell for "R" in feet

| | | | | |
|--|------|-------------|-------------|---------------|
| R Hydraulic Radius (a/p) | 0.55 | 0.55 | 0.55 | Feet |
| | | 0.167642039 | 0.167642039 | Meters |
| d Pipe Diameter | 24 | 24 | 24 | Inches |
| | | 609.6012192 | 609.6012192 | Millimeters |
| % % Full | | 97.73800% | 58.88800% | % Full |
| h Depth of Flow | | 23.45712 | 14.13312 | Inches |
| | | 595.8120396 | 358.981966 | Millimeters |
| a Area of Flow | | 3.12357209 | 1.924435027 | Square Feet |
| | | 0.290186928 | 0.178784376 | Square Meters |
| p Wetted Perimeter | | 5.679296009 | 3.499012112 | Feet |
| | | 1.731070473 | 1.066511861 | Meters |
| Partial Results | | | | |
| <i>A second solution will display when % full is at or above 50%</i> | | | | |

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Figure 4 - Two solutions for a single value of R

These two solutions (59% and 98% full) correspond to the intercepts of a horizontal line drawn at 0.55 on the Figure 5 chart below.

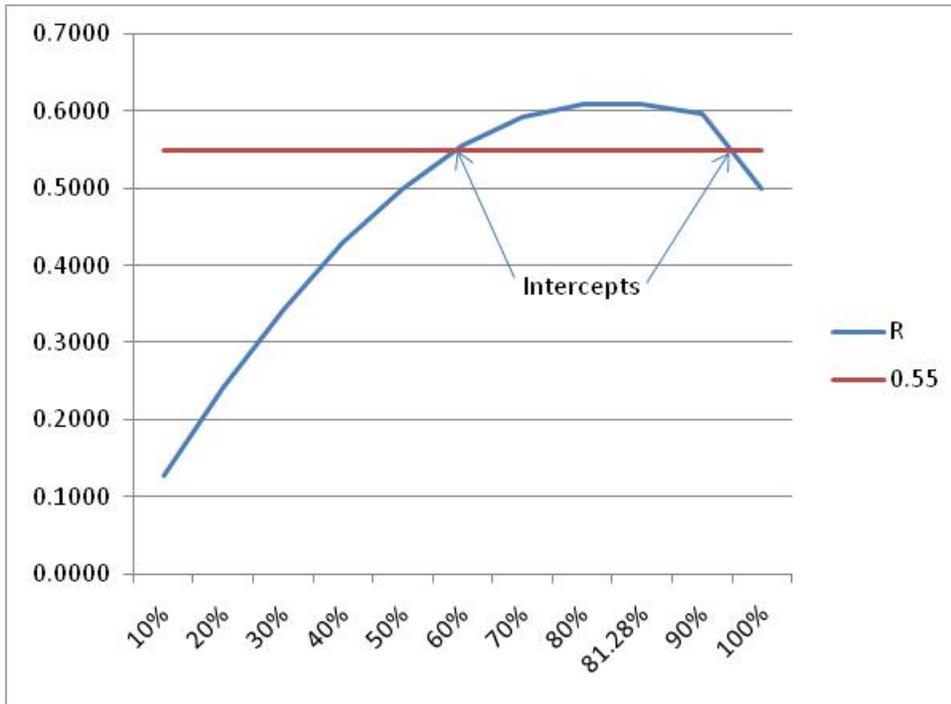

Figure 5 - Two solutions for R=0.55

Problems with two valid solutions will be covered in greater detail later in the course.

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Hydraulic Slope (S) – Is defined as the total head loss divided by the length of pipe. Figure 6 illustrates a longitudinal-section view of four different system configurations each with an identical hydraulic slope of 0.002 (0.2%). As illustrated by these examples, the hydraulic slope and the slope of the pipe need not be the same. Although all of these cases have identical hydraulic slope, only Cases 3 and 4 are also equal in velocity and quantity of flow. The so-called “inverted siphon” in Case 4 is undesirable from a maintenance standpoint but it is hydraulically the equal of Case 3.

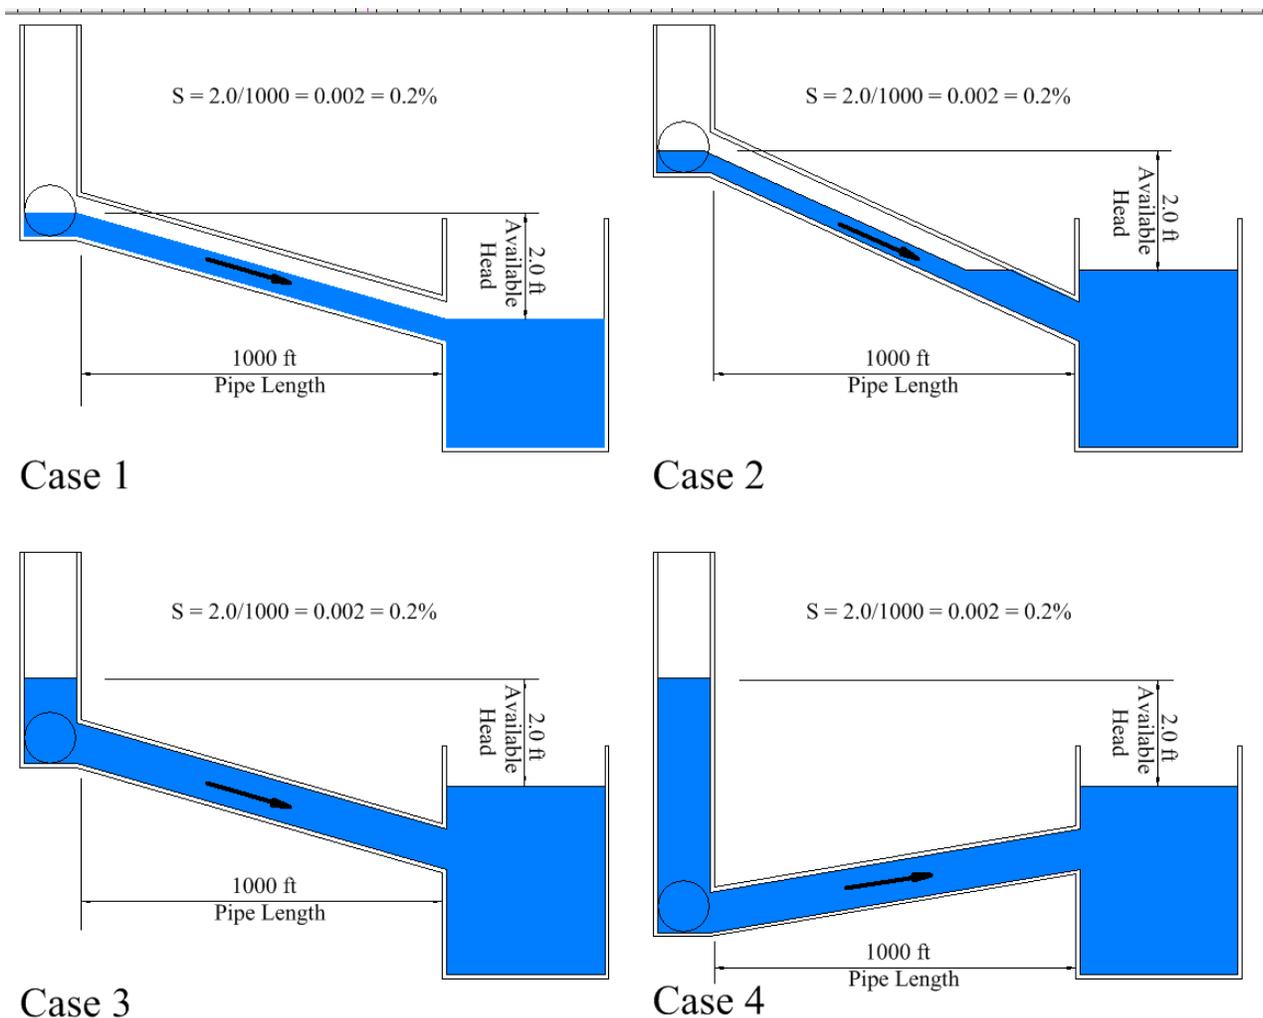

Figure 6 - Four systems with identical 0.2% hydraulic slope

The available head is the power that drives a gravity flow pipe system and it is the friction of the pipe walls that resists that power.

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Velocity (V) – The Manning Formula is a mathematical model for predicting velocity of flow in a conduit or channel. Based on Manning, the velocity of flow in a gravity system is dependent on only three things:

1. The geometry of the conduit ("R")
2. The slope of the conduit ("S")
3. The roughness of the walls of the conduit ("n")

If you know "R", "S" and "n", you can calculate velocity. In fact, using the variations of the Manning Formula shown in the beginning of this course (formulae 3, 4 & 5), any one of these variables may be calculated if the other three are known. To illustrate, using Manning-Pipe enter the following:

- [0.011] in the input cell for roughness coefficient ("n")
- [0.002] in the input cell for Hydraulic Gradient ("S")
- [0.35] in the input cell for Hydraulic Radius in feet ("R")

| | | | | | |
|----------|------------------------|-------|-------------|--|--------------------------|
| V | Velocity of flow | | 3.000450629 | | Foot/Sec |
| | | | 0.914537352 | | Meters/Sec |
| n | Roughness coefficient | 0.011 | 0.011 | | No Units |
| S | Hydraulic Gradient | 0.002 | 0.002 | | Feet/Foot or Meter/Meter |
| | | | 0.20000% | | % Slope |
| R | Hydraulic Radius (a/p) | 0.35 | 0.35 | | Feet |
| | | | 0.106681297 | | Meters |

Figure 7 - Calculating Velocity (V)

The resulting velocity is 3.000 feet per second. Now delete the entry for Roughness coefficient and enter the following:

- [3.000] in the input cell for Velocity in feet per second ("V")

| | | | | | |
|----------|------------------------|-------|-------------|--|--------------------------|
| V | Velocity of flow | 3 | 3 | | Foot/Sec |
| | | | 0.9144 | | Meters/Sec |
| n | Roughness coefficient | | 0.011001652 | | No Units |
| S | Hydraulic Gradient | 0.002 | 0.002 | | Feet/Foot or Meter/Meter |
| | | | 0.20000% | | % Slope |
| R | Hydraulic Radius (a/p) | 0.35 | 0.35 | | Feet |
| | | | 0.106681297 | | Meters |

Figure 8 - Calculating Roughness Coefficient (n)

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Note that the value of "n" is now calculated at 0.01100, matching the original entry. Testing the remaining variables gives similar results.

| | | | | |
|----------|------------------------|-------|-------------|--------------------------|
| V | Velocity of flow | 3 | 3 | Foot/Sec |
| | | | 0.9144 | Meters/Sec |
| n | Roughness coefficient | 0.011 | 0.011 | No Units |

| | | | 0.20000% | % Slope |
| R | Hydraulic Radius (a/p) | | 0.349921155 | Feet |
| | | | 0.106657265 | Meters |

Figure 10 - Calculating Hydraulic Radius (R)

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Quantity of Flow ("Q") is calculated as the product of velocity and the cross sectional area of the stream of flow. For pipes flowing full the calculation of area is simply $a = \pi r^2$ and for partially full pipes the calculation is just slightly more complex. We won't do the math here but will illustrate this by using Manning-Pipe and entering:

- [24] in the input cell for diameter in inches ("d")
- [100] in the input cell for % full ("%")Full (or [1.0] depending on your Excel setup, See Percentage note on page 4)

| | | | | | |
|----------|------------------------|------------|-------------|--|---------------|
| R | Hydraulic Radius (a/p) | | 0.5 | | Feet |
| | | | 0.152401853 | | Meters |
| d | Pipe Diameter | 24 | 24 | | Inches |
| | | | 609.6012192 | | Millimeters |
| % | % Full | 100.00000% | 100.00000% | | % Full |
| h | Depth of Flow | | 24 | | Inches |
| | | | 609.6012192 | | Millimeters |
| a | Area of Flow | | 3.141592654 | | Square Feet |
| | | | 0.291861079 | | Square Meters |
| p | Wetted Perimeter | | 6.283185307 | | Feet |
| | | | 1.91513817 | | Meters |

Figure 11 - Area of flow for a full pipe

The area of flow in square feet is 3.14159. Now change the entry for "%" full to:

- [80] in the input cell for % full ("%")Full (or [0.8] depending on your Excel setup, See Percentage note on page 4)

| | | | | | |
|----------|------------------------|-----------|-------------|--|---------------|
| R | Hydraulic Radius (a/p) | | 0.608386523 | | Feet |
| | | | 0.185438467 | | Meters |
| d | Pipe Diameter | 24 | 24 | | Inches |
| | | | 609.6012192 | | Millimeters |
| % | % Full | 80.00000% | 80.00000% | | % Full |
| h | Depth of Flow | | 19.2 | | Inches |
| | | | 487.6809754 | | Millimeters |
| a | Area of Flow | | 2.694297436 | | Square Feet |
| | | | 0.250306339 | | Square Meters |
| p | Wetted Perimeter | | 4.428594871 | | Feet |
| | | | 1.349852131 | | Meters |

Figure 12 - Area of flow for a pipe 80% full

Now, to calculate "Q", all that is needed is to multiply the area of flow by the velocity or, using Manning-Pipe enter:

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Figure 13 - Calculating Q

The resulting quantity of flow is 31.4159 cubic feet per second or 14,100 gallons per minute.

We saw earlier that the maximum hydraulic radius and velocity (but not quantity of flow) occur when a pipe is flowing 81.28% full. Now we will examine the quantity of flow to find the maximum Q. Using Manning-Pipe, we enter:

- [0.011] in the input cell for roughness coefficient ("n")

Figure 14 - Finding the "%" full that produces the maximum Q

The resulting quantity of flow is 11.9565 cubic feet per second. By changing the "%" full, we can construct Table 3 where we see that the maximum quantity of flow occurs at about 94% full. Actually, the maximum "Q" for any size circular pipe occurs when the pipe is 93.82% full. The actual quantity of flow for a pipe operating at 93%-95% full is about 7.5% greater than a full

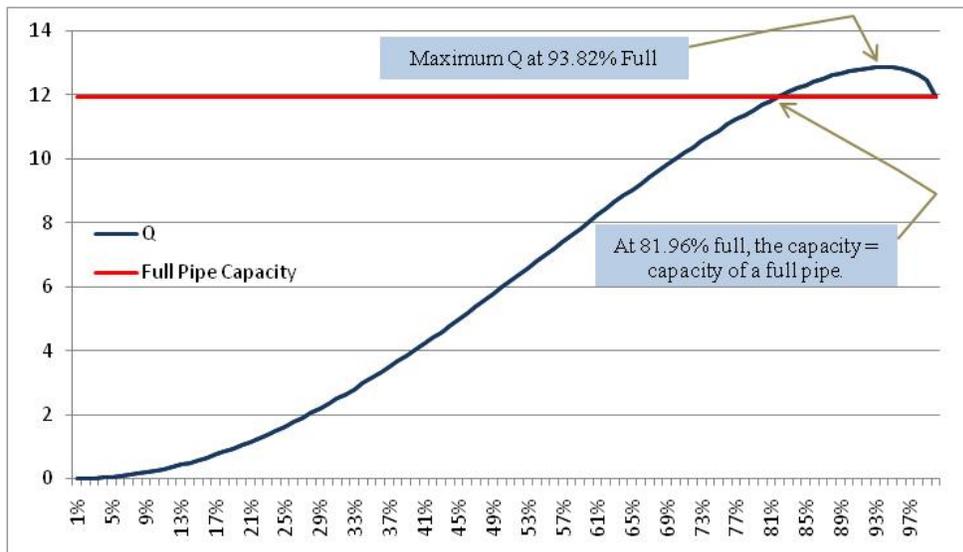

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

pipe. The reason for this somewhat counterintuitive condition is that filling that last 6% of the pipe increases the area of flow by only 2.6% while increasing the wetted perimeter by 19%. The large added wetted perimeter increases the friction loss by more than the small increase in flow area can increase the quantity of flow.

Table 3 - Finding Max "Q"

Gravity Flow in Pipes - The Manning Formula A SunCam online continuing education course

Figure 15 - Charting "Q" vs. "%" full

Figure 15 shows a plot of the values of "Q" from Table 3. The red line is a plot of the full pipe capacity, which intersects the graph of "Q" at two locations (81.96% and 100%). In other words, a pipe designed to flow full will produce the identical quantity of flow when the pipe is flowing only 81.96% full. This is true for all pipe sizes, hydraulic slopes and roughness coefficients. More on this point later.

Manning-Pipe Software is a Microsoft Excel® based program for solving the Manning Formula. The program first reads the data inputs to determine which of the variables are known and then computes as many of the missing variables as possible with the data given. Because there are many ways to compute each variable, results can often be ambiguous. Manning-Pipe will not display results when the input data supports more than one method of computing the value of a missing variable. When the input data combination produces such an ambiguity, the program will display an **"Over Determined"** message in the tracking cell.

A Word of Caution

Designing pipelines to flow 94% full in order to capture that 7.5% capacity bonus is very tempting but risky and should probably be avoided except in the most controlled environment such as a constant flow feed pipe in an industrial plant. In a public storm or sanitary sewer system, even a slight increase in the quantity of flow above the design flow condition will fill the pipe immediately and push the system into surcharge. By designing for a full pipe on the other hand, the system capacity will actually be achieved when the pipe is only 82% full (see Figure 15) leaving a safety margin of 7.5% and a useful air gap at the top of the pipe.

An air gap at the top of the pipe can often be an important part of a gravity pipeline. For example, full pipes in a sanitary sewer can often block the escape of gas, severely restricting hydraulic capacity and creating undesirable odor control conditions such as splashing, bubbling and "burping" of the venting gas into manholes. This is particularly true when manholes are sealed to prevent the inflow of surface water.

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Alternate Solutions - There are a total of 1024 (2^{10}) possible combinations of data inputs in the 10 input categories ("Q", "V", "n", "S", "R", "d", "%", "h", "a", "p"). A few of these combinations can produce two different but equally accurate sets of results. In those cases, the program will display results in both the **Solution #1** column and the **Solution #2** column to give the user the option of selecting the results that are best suited for the particular application. There are three different cases where specific input combinations can result in two solutions. You do not have to remember these cases when using Manning-Pipe because both solutions will always display when they exist. Each of the three cases is described below:

Case 1

This case is perhaps the most common way that a designer will encounter alternate solutions because it involves one of the most common sets of input data, ("Q", "n", "S" & "d"). Of the 1024 possible input combinations, only this one will produce Case 1 results. A design engineer will frequently use this combination of inputs to find the depth of flow (or "%" full) in a pipe. When the "%" Full is at or above 81.96% there will be two solutions. If the "%" Full is exactly 93.82% the two solutions will be equal. Figure 16 illustrates Case 1.

Figure 16- Alternate Solutions Case 1

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Figure 17 is a plot of the Quantity of flow vs. the percentage full for a fixed diameter pipe. The red line represents the quantity of flow for the pipe at 100% full. Any horizontal line drawn below the red line intercepts the curve only once while a horizontal line drawn above the red line and below the maximum value of "Q" will intercept the curve twice thereby yielding two alternate solutions. The shape of the curve and the percentages are the same for any pipe size.

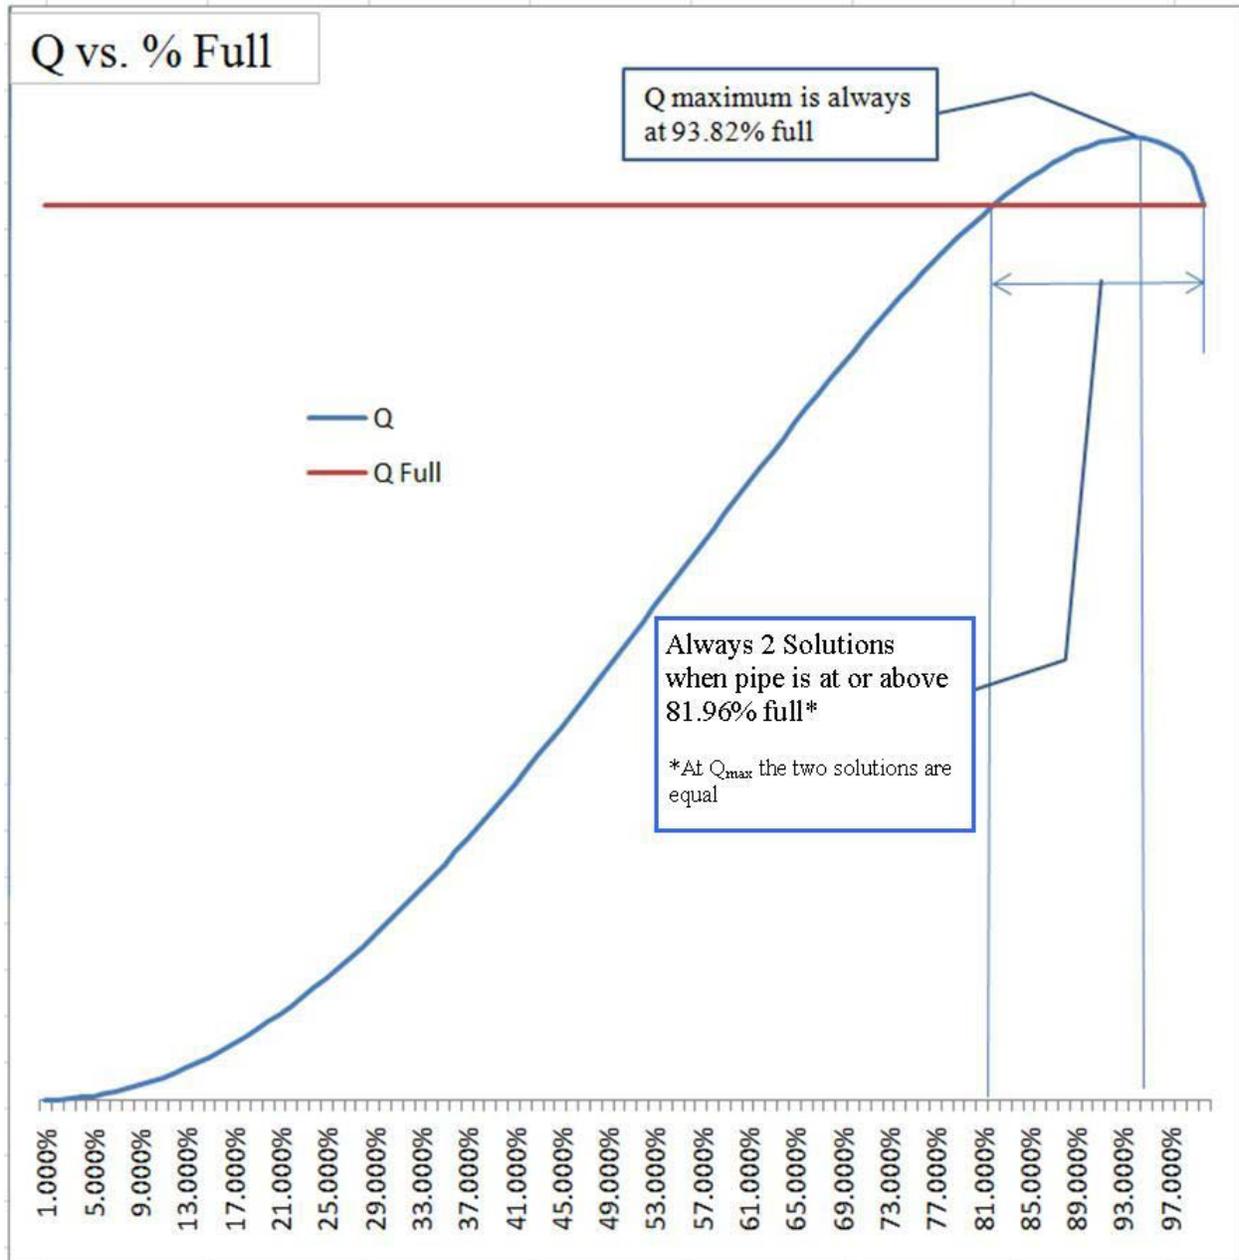

Figure 17 -- Case 1, charting "Q" vs. "% Full

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Case 2

Eleven of the 1024 possible input combinations will produce Case 2 results. Ten of these combinations involve inputs for both "R" and "d" (see Figure 18). This combination of inputs is unlikely to occur in a typical hydraulics problem because it involves the input of hydraulic radius ("R") which is seldom a known variable. Nonetheless, when a user enters data into the input cells for hydraulic radius ("R") and pipe diameter ("d") there will be two solutions whenever the pipe is calculated to be at or above half full.

Figure 19 Alternate Results Case 2b

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Figure 20 is a plot of the Hydraulic Radius vs. the percentage full for a fixed diameter pipe. The shape of the curve will be identical for any pipe size. The red line represents the hydraulic radius for the pipe at 100% full. Any horizontal line drawn below the red line intercepts the curve only once while a horizontal line drawn above the red line and below the maximum value of "R" will intercept the curve twice thereby yielding two alternate solutions. If the % Full is 81.28 the two solutions will be equal.

Variations of this case may be seen by adding entries for "Q", "V", "n" or "S" (but not "Q" and "V" together). As shown in Figure 19, inputs for the three variables "V", "n" & "S" can also combine as a replacement for "R".

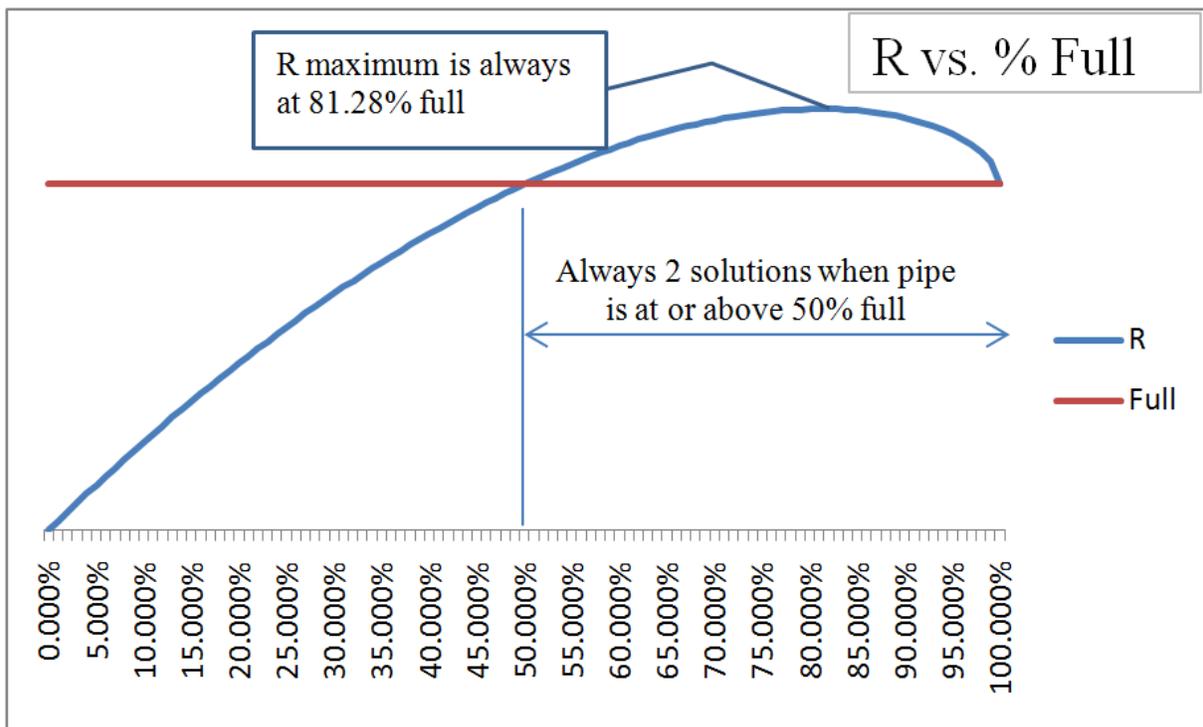

Figure 20 – Case 2, charting "R" vs. "% Full (holding "d" fixed)

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Case 3

A total of 41 of the 1024 possible input combinations will produce Case 3 results. All 41 of these involve entries for any two of the hydraulic radius ("R"), cross sectional area of the stream of water ("a") or the wetted perimeter ("p") or for other input variables that can be used to calculate "R", "a" or "p". There will be two solutions whenever the pipe is calculated to be at or above 6.1735% full. Figure 21 illustrates this point with entries for area and wetted perimeter.

Figure 21 Alternative Results Case 3

Gravity Flow in Pipes - The Manning Formula A SunCam online continuing education course

Figure 22 is a plot of the hydraulic radius vs. the percentage full of the pipe. This plot was created by calculating the hydraulic radius while holding either "p" or "a" fixed and allowing the pipe diameter to vary. Note that the curve is identical whether "p" or "a" is held constant.

Any horizontal line drawn below the red line intercepts the blue "R" curve only once while a horizontal line drawn above the red line and below the minimum value of "R" will intercept the curve twice. When the %Full is exactly 50% the two solutions will be equal.

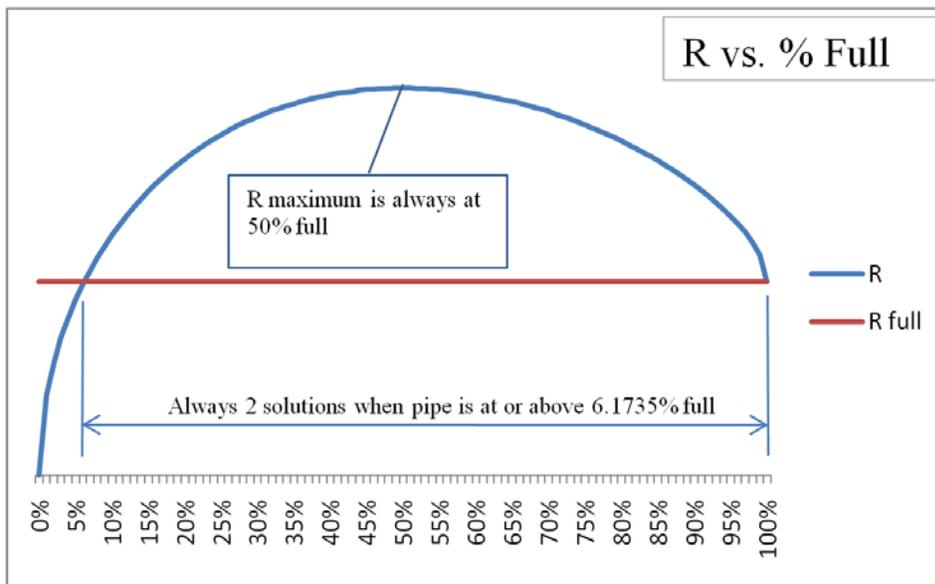

Figure 22 - Case 3, charting "R" vs. "% Full (holding "p" or "a" fixed)

Tools – Old and New

In Robert Manning's time, the slide rule was nearly 3-centuries old and still it was the latest in computing technology. Raising a number to a $2/3$ power was an arduous task then but now the simplest electronic calculator can perform the calculation in an instant and to a degree of accuracy that would have been all but unattainable in 1890.

The Manning Formula has not changed in 120 years but advances in our computing tools now make it possible for us to perform thousands of calculations faster than we can input data. Our modern computing devices give today's engineer the power to better utilize and apply those time tested tools like The Manning Formula. Whether you use the Manning-Pipe software that is the companion to this course, a simple hand calculator or a computing tool of your own making, you will be capable of performing calculations faster and more accurately than Manning could have imagined.

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

Sample Problems

The following series of four sample problems will illustrate the use of the Manning Formula and Manning-Pipe software.

Sample Problem 1

A storm sewer catch basin is planned for a public park. The design information is:

| | |
|---|---------------------|
| Quantity of flow | 3.6 CFS |
| Outfall lake surface elevation | 120.00 ft |
| Catch basin grate elevation | 124.50 ft |
| Allowed flooding above the grate | 1.5 ft. |
| The total available head is calculated as: (124.50-120.00+1.5) | 6.0' |
| Length of pipe | 500 ft. |
| The hydraulic gradient is (6.0/500) | 0.012 feet per foot |

The entire pipe will be constructed below the water surface elevation of the lake therefore, the pipe will be considered as flowing full.

Using Manning-Pipe enter:

- [3.6] in the input cell for Quantity of Flow in cubic feet per second ("Q")
- [0.022] in the input cell for roughness coefficient for CMP (corrugated metal pipe) ("n")
- [0.012] in the input cell for Hydraulic Gradient in feet per foot ("S")
- [100] in the input cell for % full ("%")Full (or [1.0] depending on your Excel setup, See Percentage note on page 4)

The resulting diameter is 14.18 inches for corrugated metal pipe (see figure 23). The next nominal size greater than the calculated diameter is 15 inches.

Figure 23 Sample Problem 1

By changing the roughness coefficient (n) to 0.013 (for concrete pipe) we see that the diameter is reduced to 11.64 inches. This means a nominal 12-inch diameter concrete pipe and a 15-inch corrugated metal pipe would be approximate hydraulic equivalents.

Now, for the concrete pipe (n=0.013), we will recalculate the hydraulic gradient using the actual pipe size by deleting the hydraulic gradient input and entering:

- [12] in the input cell for diameter in inches ("d")

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

The recalculated hydraulic gradient is 1.021% therefore the total headloss for the system is $0.01021 \times 500 = 5.105$ feet, a reduction of .895 feet in the allowed flooding above the grate. Now the allowable flooding will be slightly over 7 inches ($1.5 \text{ ft} - .895 \text{ ft} = 0.605 \text{ ft} = 7.26 \text{ in}$).

Using the corrugated metal pipe alternative ($d=15$, $n=0.022$), the hydraulic gradient would be 0.88946% therefore the total head loss for the system using CMP is $0.0088946 \times 500 = 4.45$ feet, a reduction of 1.55 feet in the allowed flooding above the grate. With the CMP alternative, the design storm will not cause any ponding above the grate ($1.50 \text{ ft} - 1.55 \text{ ft} = -0.5 \text{ ft}$).

Sample Problem 2

This problem was taken from our course on Hazen Williams formula. This will give us the opportunity to compare the results of Hazen Williams with Manning. *(The original Hazen Williams question appears in red italic)*

A small historic town exists within a perimeter levy on land that lies slightly below sea level. It uses a central canal system to collect storm water from the town and convey it to the intake side of a pump station on the perimeter of town at the levy. The pump station utilizes 3 pumps to maintain a constant elevation of water in the collector canal of 3.0 feet below mean high water. The discharge of the pump station empties into a 500-foot long pipe that in turn empties into a wide canal where the water is carried to the Gulf of Mexico for discharge.

| | | |
|----------------|--|-----------------------------------|
| <i>Pump #1</i> | <i>Operates continuously even in drought conditions to maintain the low water elevation.</i> | <i>90 Cubic Feet/Second (CFS)</i> |
| <i>Pump #2</i> | <i>Operates along with Pump #1 during routine rainfall events</i> | <i>90 CFS</i> |
| <i>Pump #3</i> | <i>Operates along with Pumps # 1 & 2 during extreme rainfall events</i> | <i>200 CFS</i> |

A federal judge has issued a ruling that the town discontinue the direct discharge into the Gulf of Mexico except in extreme rainfall events. Under the court order, pumps # 1 & 2 will pump discharge water through a 6,000-foot long pipe to a polishing pond with water surface elevation of +5.0 above mean high water and marsh filter system. Pump #3 will continue to operate without change.

Arnold de Gerabon, the design engineer for the project, evaluates the existing Pumps # 1 & 2 and determines that they are capable of producing the design volume of flow at 10 feet of head. The 3 feet of suction lift plus 5 feet for the receiving waters means the available head-loss for the new pipe would be 2-feet. He uses the Hydro-Calc tool to size the pipe by entering:

- =90+90 in the input cell for "Q" in Cubic Feet/Sec*

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

- 120 in the input cell for "C", roughness coefficient (for concrete pipe)
- =2/6000 in the input cell for "S", Feet/Foot or Meter/Meter

The resulting calculated pipe size is 99.67 inches. The nearest standard pipe size would be 108-inches (9-feet) diameter.

Here we will use Manning-Pipe to replicate the calculation using the Manning Formula. We enter:

- [=90+90] in the input cell for "Q" in Cubic Feet/Sec
- [0.013] in the input cell for "n", roughness coefficient (for concrete pipe)
- [=2/6000] in the input cell for "S", Feet/Foot or Meter/Meter
- [100] in the input cell for % full ("%")Full (or [1.0] depending on your Excel setup, See Percentage note on page 4)

Figure 24 Pipe size using existing pumps

Gravity Flow in Pipes - The Manning Formula A SunCam online continuing education course

The manning resulting calculated pipe size is 98.84 inches which is less than 1 inch or 0.8% smaller than the same calculation using Hazen Williams. Even changing the roughness coefficient to 0.012 yields a pipe size of 95.92 inches, still within 3% of the Hazen Williams results.

He then checks to see how much he could reduce the pipe size if he selects new, higher head pumps to replace Pumps # 1 & 2. Each of the new pumps is rated at 90 CFS at 28 feet of head.

He uses the Hydro-Calc tool to size the pipe by entering:

- =90+90 in the input cell for "Q" in Cubic Feet/Sec*
- 120 in the input cell for "C", roughness coefficient (for concrete pipe)*
- =(28-8)/6000 in the input cell for "S", Feet/Foot or Meter/Meter*

The resulting calculated pipe size is 62.12 inches. The nearest standard pipe size would be 66-inches (5.5-feet) diameter.

Using Manning-Pipe we enter:

- [=90+90] in the input cell for "Q" in Cubic Feet/Sec
- [0.013] in the input cell for "n", roughness coefficient (for concrete pipe)
- [= (28-8)/6000] in the input cell for "S", Feet/Foot or Meter/Meter
- [100] in the input cell for % full ("%")Full (or **[1.0] depending on your Excel setup, See Percentage note on page 4**)

The calculated pipe size using Manning is 64.19 inches as compared with 62.12 inches using Hazen-Williams. The results differ by only about 3%.

Figure 25 Pipe size using new high-head pumps

He then checks the capacity of this design by entering:

- 120 in the input cell for "C", roughness coefficient (for concrete pipe)
- 66 in the input cell for Diameter in Inches
- $= (28-8)/6000$ in the input cell for "S", Feet/Foot or Meter/Meter

The resulting calculated Quantity of flow is 211 CFS which yields a 17% factor of safety. This alternative is selected for lower initial cost and lower life cycle cost.

We use Manning-Pipe to make a similar calculation by entering:

- 0.013 in the input cell for "n", roughness coefficient (for concrete pipe)

Gravity Flow in Pipes - The Manning Formula

Figure 27 Capacity calculation using n=0.012

Sample Problem 3

The St. Cloud Development Company is planning a 40-story high-rise condominium building with 400 - 1, 2 & 3 bedroom units. The water & sewer utility has determined that neither of the gravity sewer systems nearest the building have the available capacity to serve the project. Instead, they outline a plan that requires the developer to construct a pump station and 3,000 foot force main to connect to a regional master pump station. The utility will require that the pump station and force main be oversized to accommodate other nearby properties with similar development potential.

Barbara Johnson, P.E., the consulting engineer for the project calculates that the peak sewer flow from the building is 175 gallons per minute (gpm) and she is not convinced that the pump station

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

and force main is really necessary. She persuades the developer to allow her to conduct a capacity study on the nearby gravity sewers to calculate the available capacity and verify or refute the utility determination.

Ms. Johnson first contacts the chief engineer for the utility company to obtain record drawings for the two systems and to establish the establish the peak day of week and hour of day for the two systems. She plans four inspections to measure the depth of flow in each of the sewer lines. Three of the inspections are scheduled at the peak day/hour for the following 3-weeks and one is planned for measuring flows at 2:00 AM after rainstorms have increased the elevation of groundwater. This fourth inspection will help distinguish between the normal domestic flow and flow caused by the infiltration of groundwater. (At 2:00 AM a gravity sewer that does not suffer groundwater infiltration will usually have very low flows.)

The findings are:

| | System "A" | System "B" |
|---------------------------------|-----------------|--------------|
| Pipe Size | 8" | 16" |
| Pipe Material | Asbestos Cement | Ductile Iron |
| Average daytime flow depth (in) | 7.0" | 12.5" |
| Slope (downstream) | 0.4% | 0.14% |
| Average 2:00 AM flow depth (in) | 4.5 | 1.2 |

She uses Manning-Pipe software to calculate the flow for each of the systems. For System "A", she enters:

- [0.011] in the input cell for "n", roughness coefficient (don't enter the [brackets])
- [.004] in the input cell for "S", Hydraulic gradient (ft/ft)
- [8] in the input cell for pipe diameter "d" (in)
- [100] in the input cell for % full ("%")Full (or [1.0] depending on your Excel setup, See Percentage note on page 4)

The resulting capacity at 100% full is 405 gpm.

She then changes the "%" Full input cell to [=7/8] and thus calculates the average peak hour flow at 426 gpm which is 21 gpm higher than the capacity of the pipe flowing full.

Figure 28 System “A” Average daytime flow volume (gpm)

(For round pipe, the maximum quantity of flow occurs at approximately 93.82% full and any pipe flowing greater than 81.96% and less than 100% full will have a greater capacity than the same pipe flowing 100% full. See Figure 15)

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

To calculate the amount of flow attributable to infiltration she changes the "%" Full input cell to [=4½ / 8] to calculate 246 gpm (see Figure 29).

| Variable | Inputs | Solution #1 | Solution #2 | Units |
|---------------------------------|-------------|-------------|----------------------------|----------------------------|
| Q Quantity of Flow | | 0.548509093 | | Cubic Foot/Sec |
| | | 246.187981 | | Gallons/Minute [US] |
| | | 0.354510691 | | MGD (Million gal/day) [US] |

Figure 29 – Calculating Infiltration

She follows the same procedure for the System “B” pipe using a roughness coefficient of 0.012 with the following results:

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

| | System "A" | System "B" |
|--------------------------------------|-----------------|--------------|
| Pipe Size | 8" | 16" |
| Pipe Material | Asbestos Cement | Ductile Iron |
| Average daytime flow depth (in) | 7" | 12.5" |
| Slope (downstream) | 0.4% | 0.14% |
| Total capacity (gpm) | 405 | 1396 |
| Average daytime flow volume (gpm) | 426 | 1332 |
| Available capacity (gpm) | -21 | 64 |
| Average 2:00 AM flow depth (in) | 4.5 | 1.2 |
| Average 2:00 AM flow volume (gpm) | 246 | 16 |
| Available capacity plus infiltration | 225 | 80 |

Table 4 - Calculating Available Capacity

In her report to the developer, Johnson confirmed that the existing gravity systems did not have sufficient available capacity for the project unless repairs were made to stop the infiltration into System "A". The cost of those repairs was significantly lower than pump station and force main alternative and the benefit to the utility would be greater because the repairs would eliminate the cost of treating the infiltrated groundwater.

Sample Problem 4

The James River Public Utilities Authority is retiring the ancient water treatment operation at their Alpha Water Treatment Plant and relocating that function to the new Lambda Water Treatment Plant 3,000 feet away. The ground storage tanks and high service distribution pumps at the Alpha Plant are to remain in service receiving finished (treated) water from Lambda at a constant rate of 80 million gallons per day (MGD) through two low service transfer pumps at Lambda and a 36" diameter prestressed concrete pressure pipe connecting the two plants.

Ed Davis is the new chief engineer for the utility and it is his job to build the new plant and complete the changeover. As he reviewed the plans on his first day on the job he noticed that the new plant site has a ground elevation that is 40 feet above the old plant which means there is a possibility that the feed from Lambda to Alpha could be by gravity flow. He uses Manning-Pipe and enters:

- [80] in the input cell for "Q", quantity of flow in MGD
- [012] in the input cell for "n", roughness coefficient (for concrete pipe)
- [=40/3000] in the input cell for "S", Feet/Foot or Meter/Meter

Gravity Flow in Pipes - The Manning Formula
A SunCam online continuing education course

- [100] in the input cell for % full ("%")Full (or [1.0] depending on your Excel setup, See Percentage note on page 4)

| Variable | Inputs | Solution #1 | Solution #2 | Units |

Figure 30 Sizing a gravity alternative

The resulting calculated pipe size is 41.7 inches in diameter or 42 inches nominal pipe size. This plain reinforced 42-inch concrete pipe, Davis reasons, will actually be less costly and more reliable than the pressure rated 36-inch pre-stressed concrete pipe that was shown on the plans, plus the utility will be able to eliminate purchasing, installing, maintaining and operating the two low service transfer pumps.
